Mind your spreadsheets: Tips to improve your data governance before an incident

05 mai 2022

Even the most secure organizations fall victim to cyber attacks. To be prepared, organizations need to identify and secure or delete certain high-risk forms of data on their systems.

Cyber criminals have been cashing in on organizations' loose information governance practices since the rise of so-called "double extortion" in 2020 in which threat actors encrypt key systems, steal data and demand a ransom in exchange for decryptors and deletion. In this article, we explain how ungoverned data collections can complicate an incident response, and provide helpful tips to improve data management.

Threats

Cyber threat actors now often steal data and hold it for ransom, offering to delete it only after payment of a ransom commensurate with the data's sensitivity.

Although theft of databases does occur, it is common for threat actors to search for and find sensitive files from network file shares. All too often, an organization's file share serves as a digital "junk drawer," storing random files that do not fit squarely into a records retention scheme. This is pay dirt for the threat actor. Sophisticated threat actors will use automated means to harvest loose files from a variety of network locations – endpoints, file shares and e-mail accounts, for example. They will then present unstructured (or "flattened") lists of tens or hundreds of thousands of files back to organizations in an attempt to impede proper valuation and use time pressure to extort a higher payment.

Whether or not the threat actors dump these large caches of data on the dark web, the response can be very arduous because notification to those impacted must usually follow. It is often necessary to send all or most of the data cache for processing e-discovery to identify all the personal information exposed and who it belongs to.

E-discovery has become a major incident response cost, and victimized organizations have a key stake in limiting its scope. The number of affected individuals drives notification and a number of related costs, and is also a key factor in the exposure to

legal claims. Bluntly, an incident with a small group of affected individuals is a much less attractive class action target.

Formal records, scheduled and classified according to their sensitivity, are not the problem. Given they are under governance, formal records tend to be secured appropriately, including by encryption. It is the treatment of file copies, in particular copies of files that are “transitory” or “loose” and ungoverned that tend to cause the size of affected populations to balloon.

Consider the creation of an export file for a project that involves migrating data from one system to another. It contains information about 20,000 individuals, yet is left unencrypted on a file share or on a single employee’s workstation. Files like this – and spreadsheets in particular – build up on a network and can double the population of individuals affected by a network compromise.

What organizations need to do

Organizations must recognize this particular threat and take steps to reduce their ransomware blast radius. In other words, they should assume the data on their networks is at risk of being stolen and take steps to minimize the potential impact of theft.

This can be done through a range of technical means, including through the implementation of segmentation and privilege minimization. Our focus here, however, is on records and information governance, and we make two suggestions:

1. **Organizations should implement a workable policy to govern user behaviour.** Many organizations have implemented clean desk and convenience copy rules to govern physical copies. The rule we contemplate is the electronic equivalent. We say “workable” because any rule that governs the use of sensitive convenience copies has the potential to impede productivity. A good rule will address the risk reasonably, leverage available technology and be acceptable to users.
2. **Organizations should consider conducting periodic network scans.** This means scanning the network to find problem files before a threat actor does. These scans serve the dual purpose of identifying problematic files and ensuring adherence to data policies. There are tools and services available, and like most security solutions, strong implementation is key and no tool is likely to do all the work. With a proper investment and good implementation, however, an organization is likely to eradicate the “low hanging fruit” and mitigate a significant degree of its risk.

Takeaways

Ransomware regularly involves data theft. The threat actor will search for sensitive data wherever it resides. Organizations that have policies and controls to protect their most sensitive data may still have ungoverned loose data on their systems. To avoid a costly e-discovery exercise and unexpectedly large notification obligations, organizations should adopt digital clean desk and convenience copy rules and engage in regular network scanning.

BLG | Vos avocats au Canada

Borden Ladner Gervais S.E.N.C.R.L., S.R.L. (BLG) est le plus grand cabinet d'avocats canadien véritablement multiservices. À ce titre, il offre des conseils juridiques pratiques à des clients d'ici et d'ailleurs dans plus de domaines et de secteurs que tout autre cabinet canadien. Comptant plus de 725 avocats, agents de propriété intellectuelle et autres professionnels, BLG répond aux besoins juridiques d'entreprises et d'institutions au pays comme à l'étranger pour ce qui touche les fusions et acquisitions, les marchés financiers, les différends et le financement ou encore l'enregistrement de brevets et de marques de commerce.
